- 4) A slit, selecting only a short range of vertical angles, selects photons from a small range of source points along the bunch.
- 5) A second crab cavity, a betatron phase advance of 2p after the first, kicks the tail up and the front down, compensating the vertical oscilations.

In a quadrupole particles are focused in one plane and defocused in the other plane. Other modes of strong focusing are not possible.

- i) Sextupole fields hardly influence the particles close to the center, where one can linearize in x and y.
- ii) In linear approximation a by Δx shifted sextupole has a quadrupole field.

$$\vec{B} = -\vec{\nabla} \psi = \Psi_3 3 \begin{pmatrix} 2xy \\ x^2 - y^2 \end{pmatrix} \quad \text{iii})$$

When Δx depends on the energy, one can build an energy dependent quadrupole.
